

CPE 325: Embedded Systems Laboratory

Laboratory #8 Tutorial

UART Serial Communications

Aleksandar Milenković

Email: mlenka@uah.edu

Web: <http://www.ece.uah.edu/~mlenka>

Objective

This tutorial will introduce communication protocols used with MSP430 and other devices. Specifically, it will cover asynchronous serial communication using USCI peripheral. You will learn the following topics:

Configuration of the USCI peripheral device for UART mode

Utilization of the USCI in UART mode for serial communication with a workstation

Understanding of workstation clients interfacing serial communication ports (putty) and UAH serial communication application

Notes

All previous tutorials are required for successful completion of this lab. Read CPE323 lecture discussing [UART Communication](#).

1 Serial Communication

An MSP430-based platform can communicate with another system, such as a personal computer, using either the synchronous or asynchronous communication mode. For two devices to communicate synchronously, they must share a common clock source. In this lab, we are going to interface a MSP430 with a personal computer using an asynchronous communication mode. Since the two devices do not share a clock signal, there should be an agreement between the devices on the speed of the communication before the actual interface starts.

To configure the MSP430 in UART mode, the internal divider and the modulation register should be initialized appropriately. The internal divider is calculated by dividing the clock by the baud rate. But, the division of the clock by the baud rate is usually not a whole number. Therefore, to take account of the fraction part of the division, we use the modulation register. The value in the modulation register is calculated in such a way that the time it takes to receive/transmit each bit is as close as possible to the exact time given by the baud rate. If the appropriate modulation value is not used, the fraction part of the division of clock frequency by the baud rate will accumulate and eventually make the two devices unable to communicate. An MSP430-based platform can be connected to a PC machine using the HyperTerminal application in Windows.

Let us consider a program that sends a character from the PC to the MSP430F5529 microcontroller and echoes the character back to the PC (Figure 1). Since we cannot connect the two systems (our PC and the microcontroller) to the same clock source, we should use the UART mode. The USCI peripheral can be utilized for that purpose. The communication speed is 115,200 bits/s (one-bit period is thus $1/115,200$ or ~ 8.68 μ s). The USCI clock, UCLK, is connected to SMCLK running at 1,048,576 Hz. To achieve the baud rate of 115,200 bits per second, the internal divider registers are initialized to UCA0BR0=0x09, and UCABR1=0x00, because $1,048,576/115,200 = 9.1 \sim 9$. Additionally, the modulation register, UCA0MCTL, is set to 0x02 (bit 0 of the field UCBRSx is set to 1). See the reference manual (Table 36.4 in <https://www.ti.com/lit/ug/slau208q/slau208q.pdf>) for more common combinations of clock source and baud rate and values for baud rate control registers. Also, the reference manual gives details on how the right value in UCA0MCTL is determined (the idea is to continuously minimize probability of erroneous detection at the receiver side).

Figure 1 shows an implementation using polling. The function UART_setup() is configuring USCI in UART mode: 8-bit characters, no parity, 1 stop bit, and the baud rate is set as described above. Please note that we follow recommended sequence of steps for USCI initialization – the SWRST bit in the control register remains set during initialization and it is cleared once the initialization is over. The main program loop is an infinite loop where we use polling to detect whether a new character is received. The program is waiting in line 71 for new character to be received. When a character is received in the UCA0RXBUF register, the UCA0RXIFG bit is set. Before the character is echoed back through the serial interface, we first check whether the USCI's transmit data buffer is empty (line 73). When the transmit buffer is empty, we proceed with copying the received character that is in UCA0RXBUF into UCA0TXBUF. The LED1 is toggled before we go back to the main loop.

```

Figure 1. Echoing a Character Using the USCI in UART Mode and Polling

Figure 2 shows the program that performs the same task, but this time an interrupt service routine tied to the USCI receiver is used. In the main program the USCI is configured to generate an interrupt request when a new character is received. Whenever a character is received and loaded into UCA0RXBUF, the interrupt flag UCA0RXIFG is set and interrupt request is raised. The main program does nothing beyond initialization – the processor is in a low-power mode 0 (LPM0). What clock signals are down in this mode?

All actions in this implementation occurs inside the service routine. The processor wakes up when a new character is received, and we find ourselves inside the service routine. In the ISR before writing the new character to UCA0TXBUF to transmit back to the workstation, we need to make sure that it is indeed empty to avoid loss of data. The UCA0TXIFG interrupt flag is set by the transmitter when the UCA0TXBUF is ready to accept a new character. Note: here we do polling on transmit buffer inside the receiver ISR. When the UCA0TXBUF is ready (UCA0TXIFG flag is set), the content from UCA0RXBUF is copied into the UCA0TXBUF. The LED4 is toggled. When exiting the ISR, the original PC and SR are retrieved bringing the processor back in the LPM0.

Figure 2. Echoing a Character Using the USCI Device

2 Real-Time Clock

In this section we will describe a program that implements a real-time clock on the MSP430 platform (Figure 3). The time is measured from the beginning of the application with a resolution of 100 milliseconds (one tenth of a second). The time is maintained in two variables, unsigned int sec (for seconds) and unsigned char tsec for tenths of a second. What is the maximum time you can have in this case? To observe the clock we can display it either on the LCD or send it serially to a workstation using a serial communication interface. In our example we send time through a serial asynchronous link using the MSP430's USCI (Universal Serial Communication Interface) device. This device is connected to a RS232 interface (see MSP EXP430F5529LP schematic) that connects through a serial cable to a PC. On the PC side we can open putty application and observe real-time clock that is sent from our development platform.

The first step is to initialize the USCI device in UART mode for communication using a baud rate 9,600 bits/sec. The next step is to initialize Timer_A to measure time and update the real-time clock variables. The Timer_A ISR is used to maintain the clock and wake up the processor. In the main program, the local variables are taken and converted into a readable string that is then sent to the USCI device.

```

Figure 3. Display Real-Time Clock Through UART

Please note that `sprintf` with modifiers requires full `printf` support. This should have been already set by you when creating the project. If you did not, it is under MSP430 Compiler->Advanced Options->Language Options as shown in Figure 4.

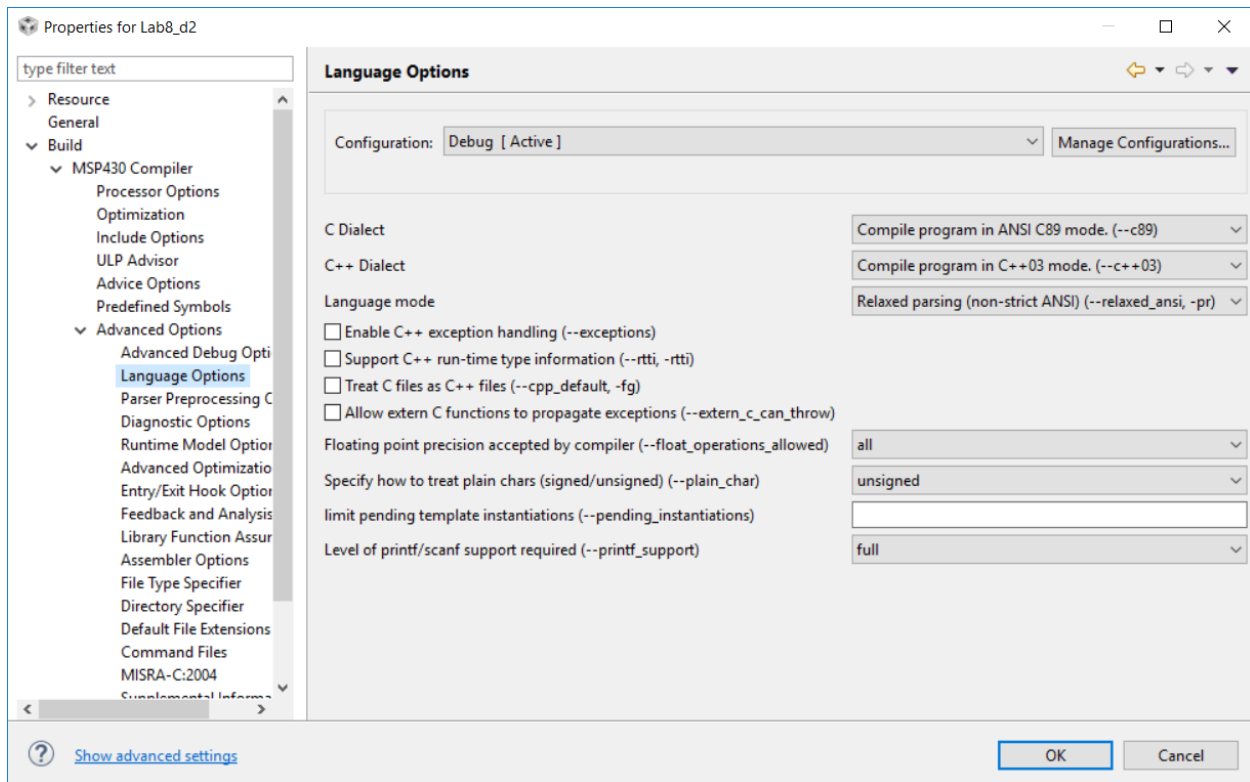

Figure 4. Setting Code Composer to Support sprintf

3 Putty versus Serial App

As a final note, it's important to keep in mind how information is being sent through the UART connection. As we begin this lab, we will generally use the Putty application (available for download at <http://portal.mhealth.uah.edu/public/index.php/serial-port-application>). The Putty application can only display ASCII characters. Since the UART communication protocol sends 8-bit chunks of information, the USCI peripheral has buffers that are best suited to sending or receiving 1-byte size data (with the added stop bits, etc.). It is simplest, therefore, to send and receive ASCII characters as they are a convenient 8-bit size. Putty can only handle character data types. If it receives non-character information, it will be interpreted as characters and gibberish will appear on the screen.

However, we do not always want to send characters – we often want to send and view data of different types (ints, floats, etc.). To view this type of information, we can use the convenient UAH Serial Application developed by our former student Mladen Milosevic. This application translates serial packets that are sent to it, and it can graphically represent the data versus time. Being able to construct packets with the MSP430 and read them with a software application is an important part of communication.

Because the UART protocol specifies that data is sent in 1-byte chunks, we must create a larger structure of information that we'll send. This is called a packet. The packet consists of predetermined bytes that we construct and tell the receiving software application how to

Figure 5 shows a demo program for sending a floating-point variable through UART. The 4-byte float variable is sent in a 5-byte packet: header (1-byte) and 4-byte data (LSB byte is sent first). The variable is increased by 0.1 every second with modulus 10.0 and reported through UART as shown in the WDTISR.

91     for(index = 0; index < 4; index++)
92     { // Send 4-bytes of myData
93         UART_putCharacter(myPointer[index]);
94     }

```

```

95
96 // Update myData for next transmission
97 myData = (myData + 0.1);
98 if(myData >= 10.0)
99 {
100     myData = 0.0;
101 }
102 }
103

```

Figure 5. MSP430 Program for Sending Floating-Point Data (UAH Serial App)

Figure 6 shows how to properly configure UAH Serial App for viewing the RAMP signal. We are using a single channel, the size of the packet is 5 bytes, we are plotting one sample at a time (they are arriving rather slowly in this example). Figure 7 shows the RAMP signal in the UAH Serial App sent by the program from Figure 5.
